**Introduction**

- Calves are born deficient in fat soluble vitamins and depend upon colostrum and milk to provide adequate vitamins E and A. Sun exposure is required for adequate systemic vitamin D production since vitamin D content of colostrum and milk is typically very low.
- In early spring, gestating beef cows consuming stored roughages that contain low levels of fat-soluble vitamins, typically supply lower levels of fat-soluble vitamins E and A in colostrum and milk compared to gestating cows grazing lush pasture (Hidiroglou et al., 1973). While mineral/vitamin supplements may contain vitamin A and vitamin D, levels of vitamin E are typically very low (0 to 220 I.U. vitamin E per kg mineral)
- Gestating dairy cows are typically supplemented with higher levels of fat-soluble vitamins pre-partum compared to beef cows, especially vitamin E.
- Newborn calves deficient in fat-soluble vitamins can exhibit weak-calf syndrome, muscle weakness and diarrhea after birth (Waldner, 2007; Radostits, 1991).
- Injecting fat-soluble vitamins at birth is a means to enhance fat-soluble vitamin status during the first few weeks after birth (Krueger, et al. 2014).
- Two experiments were conducted to measure effectiveness of **VITAL E®-Newborn** (Stuart Products, Inc.) on fat-soluble vitamin status in newborn beef and dairy calves.

One mL of **VITAL E®-Newborn** contains 500 I.U vitamin E (d-alpha-tocopherol), 50,000 I.U. vitamin A (retinyl palmitate), and 50,000 I.U. vitamin D (cholecalciferol).

**Methods**

In experiment 1, randomly selected newborn Angus beef calves (n= 4) were not injected and others (n= 4) were injected S.O. with 5 mL **VITAL E®-Newborn**. Serum samples were obtained initially and days 1, 2, and 7 post-injection and analyzed for α-tocopherol, total vitamin A (retinyl palmitate), and 25-OH-D3.

In experiment 2, newborn Holstein dairy calves (n= 4) were not injected and others (n=7) were injected S.O. with 5 mL **VITAL E®-Newborn**. Serum samples were taken 62 h post-injection and analyzed for α-tocopherol, retinol and 25-OH-D3.

Serum was analyzed for Vitamin E and vitamin A by Veterinary Diagnostic Laboratory, Iowa State University, Ames, and for 25-OH-D and Heartland Assays, Ames, Iowa. Paired t-test was used to determine differences between treatments.

**Discussion**

- Beef and dairy calves responded similarly to the injection.
- Increase in vitamin A status was mainly due to increase in retinyl palmitate levels. Retinol did not increase significantly.
- Vitamin D status continued to increase 7-days post injection in beef calves.
- Vitamin E status was highest 24 hours post-injection in beef calves.

**Results-Beef Calves**

**Serum Vitamin A Status-Beef Calves**
- Retinol + Retinyl Palmitate
- All treated calves were injected S.O. with 5 mL **VITAL E®-Newborn** to supply each calf:
  - 2,500 I.U. vitamin E (d-α-tocopherol)
  - 250,000 I.U. vitamin A (retinyl palmitate)
  - 250,000 I.U. vitamin D (cholecalciferol)

**Results-Dairy Calves**

**Serum Retinol Status-Dairy Calves**

**Serum Vitamin D Status-Dairy Calves**

**Serum Vitamin E Status-Dairy Calves**

**Conclusion**

- Injecting newborn calves with a bioavailable source of fat-soluble vitamins is an excellent method to assure that newborn beef and dairy calves have adequate levels of these critically important vitamins after birth.
